1 Problem

2 Solution

- Fixed Point Iterations
- Newton's Method
- Secant's Method

Problem Statement

Find the roots of the equation $(x + 2)^3 = 2x(x^2 - 1)$

Fixed Point Iterations

First, we simplify the given equation,

$$x^3 - 2x^2 - 6x - 8 = 0 \quad (3.1)$$

We can solve the above equation using fixed point iterations. First we separate x , from the above equation and make an update equation of the below sort.

$$x = g(x) \implies x_{n+1} = g(x_n) \quad (3.2)$$

Applying the above update equation on our equation, we get

$$x_{n+1} = \frac{x_n^3 - 2x_n^2 - 8}{6} \quad (3.3)$$

Now we take an initial value x_0 and iterate the above update equation. But we realize that the updated values always approach infinity for any initial value.

Fixed Point Iterations

Newton's Method

We can use Newton's Method for solving equations.

$$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)} \quad (3.4)$$

Where we define $f(x)$ as,

$$f(x) = x^3 - 2x^2 - 6x - 8 \quad (3.5)$$

$$f'(x) = 3x^2 - 4x - 6 \quad (3.6)$$

Thus, the new update equation is,

$$x_{n+1} = x_n - \frac{x_n^3 - 2x_n^2 - 6x_n - 8}{3x_n^2 - 4x_n - 6} \quad (3.7)$$

Taking the initial guess as $x_0 = 1$, we can see that x_n converges at the 43rd iteration with x as,

$$x = 4 \quad (3.8)$$

Figure

Secant's Method

We can use also Secant's Method for solving equations.

$$x_{n+1} = x_n + f(x_n) \frac{x_n - x_{n-1}}{f(x_n) - f(x_{n-1})} \quad (3.9)$$

Newton's method is very powerful but has the disadvantage that the derivative may sometimes be a far more difficult expression than $f(x)$ itself and its evaluation therefore it may be more computationally expensive.

The secant's method is more computationally cheap as the equation of the derivative is avoided by taking 2 starting points.

Taking the initial guesses as $x_0 = 1, x_1 = 2$, we see that x_n converges in 36 iterations with x as,

$$x = 4 \quad (3.10)$$
